

Phishing

Is a type of cyber-attack where attackers masquerade as a trusted entity to trick individuals into revealing sensitive information such as login credentials, financial details, or personal data. It is commonly carried out through emails, fake websites, text messages, or phone calls.

Common types of Phishing:

Email Phishing: Fake emails that appear to come from a legitimate source to steal credentials or deliver malicious software.

Spear Phishing: These are targeted attacks on specific individuals or organisations using personalized information:

Whaling: High-level phishing targeting executives or high-profile individuals.

Smishing: Fraudulent text messages with malicious links or requests for sensitive data.

Vishing: Phone scams where attackers pretend to be a trusted entity e.g. calls for banks, IT dept.

Phishing emails are highly successful and are among the most effective cyber-attack methods. Their success varies based on the target sophistication, attack method, and security awareness of the individual receiving the email.

Factors that increase phishing email success:

1. **Social Engineering:** Attackers use urgency, fear, or curiosity for example urgent password reset, fake invoices
2. **Personalisation:** Spear phishing emails normally include personal details making them highly successful.
3. **Poor Cybersecurity awareness:** Employees without are more susceptible to clicking on fake emails

How to identify a phishing email: There are initial indicators that can be used to determine/warn a phishing attempt. These include

- **Urgent or Threatening language:** Phishing emails use language that prompts immediate action for example account closures, or urgent changing of password/s.
- **Generic Salutation:** "Dear Customer" is a common salutation that is used in phishing emails. Legitimate organisations normally personalize emails.
- **Look-a-like Sender Information:** Phishing emails may come from an address that closely resembles a legitimate organisation but with subtle differences, for example, unusual domain names, and misspellings.
- **Suspicious Links and Attachments:** It is good practice to hover over any links without clicking them this will show the URL be sure it matches what you expect before clicking. As for attachments, it is advisable to get an expert opinion if unsure.
- **Poor Grammar/Spelling mistakes:** Multiple errors in the grammar and spelling mistakes can be a red flag. Legitimate professional organizations have a high standard of communication

Further analysis can be carried out on the suspected email to determine if it is a phishing attempt by looking at the Email header.

Email headers are pieces of metadata that provide detailed information about the email's origins, route taken, and handling before it reaches the final destination. Some of the details contained in the email headers are

- **Sender and Recipient information:** Email address of the sender and the receiver
- **Routing data:** A series of “Received” lines that trace the email’s journey across different mail servers, indicating the path it took and the timestamps at each step
- **Authentication results:** Information from mechanisms like SPF, DKIM, and DMARC help verify the sender's identity and access the email's legitimacy.
- **Message Metadata:** This data contains the Subject, date, time the email was sent, and a unique message ID which can be used for tracking the email.

What is SPF, DKIM, and DMARC?

SPF, DKIM, and DMARC are three email authentication methods. Together these can be used to identify spammers, phishing emails, and other unauthorised parties that send emails.

How does SPF work?

Sender Policy Framework (SPF): Is a way for the domain to list all the servers they send emails from. SPF records list all the IP addresses of all the servers that are allowed to send emails from an organization’s domain. Mail servers that receive emails check against the SPF record before passing it on to the recipient's inbox.

How does DKIM work?

Domain Keys Identified Mail (DKIM) enables domain users to automatically sign emails for their domain. The DKIM signature is a digital signature that uses public key cryptography to verify that the email came from the domain. The DKIM record stores the public key and the mail servers receiving emails from the domain can check this record to obtain the public key. The private key is kept secret by the sender who signs the email header with this key

How does DMARC work?

Domain-based Message Authentication and Conformance (DMARC) tells the receiver that receives emails what to do given the results after checking SPF and DKIM. The DMARC policy can be set in various ways one of which is to quarantine emails that fail SPF or DKIM or both.

Part 2

Demonstration of checking a suspicious phishing email.

Example 1

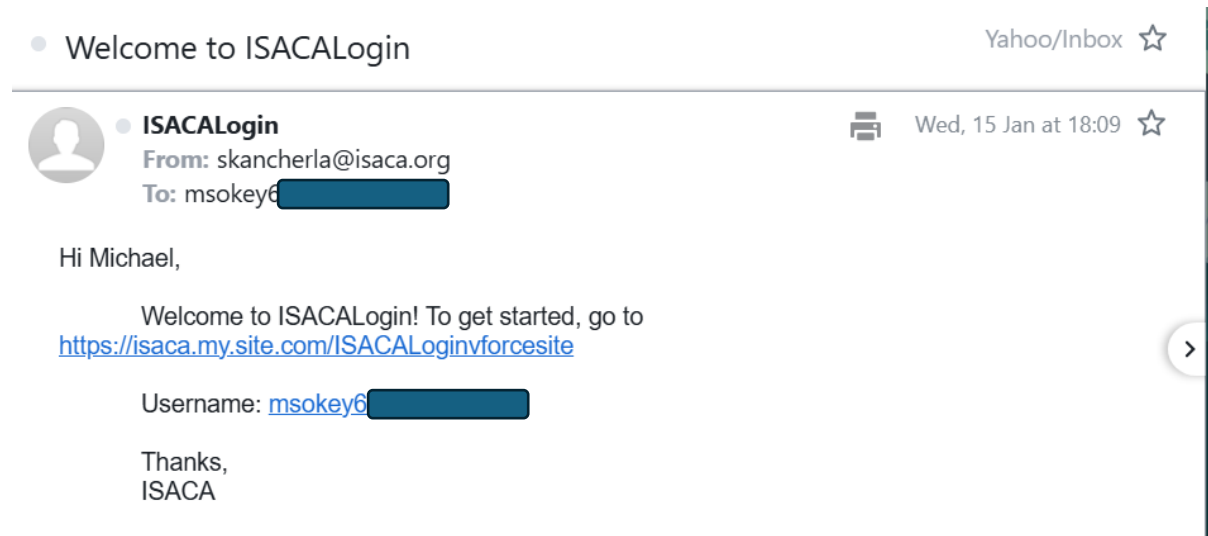

Figure 1

The above email was sent to all ISACA members. Most members thought it was a phishing email. To investigate this, click on the 3 dots next to Spam then click on View raw message

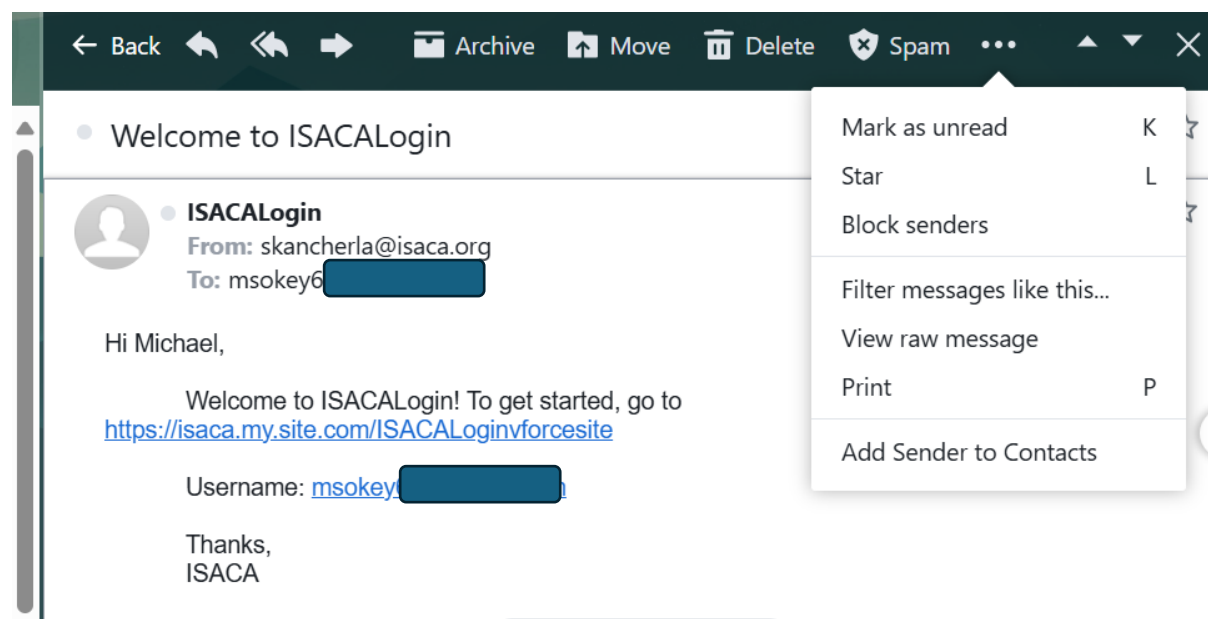

Figure 2

The raw format of the email will be displayed - Figure 3

Figure 7

The SPF, DKIM and DMARC show none, this is widely considered to be a “fail” and this would trigger further investigation. This email most likely should be deleted from the user's inbox

The links did not produce any results however the return email was flagged as suspicious.

The screenshot displays a security analysis tool interface for the URL `http://solutionteamrecognizd03@gmail.com/`. The top section shows a community score of 0/96 and a status of 200. A message indicates that no security vendors flagged this URL as malicious. Below this, the URL is analyzed as `text/html` with tags for `external-resources`, `multiple-redirects`, and `trackers`. The interface has tabs for **DETECTION**, **DETAILS**, and **COMMUNITY**. A banner encourages joining the community for insights and checks. The **Crowdsourced context** section shows a **LOW 1** risk level with a warning icon and text: "Cmstar Downloader: Lurid And Enfal's New Cousin - according to source ArcSight Threat Intelligence - 1 year ago". It also provides contextual indicators, including the domain's Alexa rank (1589) and a VirusTotal link. The **Security vendors' analysis** section shows a **Suspicious** flag from ArcSight Threat Intelligence, while Abusix and another vendor are marked as **Clean**.

Security vendors' analysis
ArcSight Threat Intelligence: Suspicious
Abusix: Clean
[Vendor]: Clean

Figure 8

This suspicious flag warrants further investigation.

Example 3

In this email, the SPF, DKIM, and DMARC all passed but on further investigation, the links were flagged as malicious.

From:	"ISACA" <isaca@tr.isaca.org>
To:	<msokey6[REDACTED]>
Subject:	Please disregard "Welcome to ISACALogin" email
SPF:	pass with IP Unknown! Learn more
DKIM:	pass with domain tr.isaca.org pass with domain s11.y.mc.salesforce.com Learn more
DMARC:	pass Learn more

Figure 13

Figure 13 is obtained by copying the raw format of the email in Figure 5

Conclusion

For all the emails that were flagged, it is recommended that the user who received the email to change the password. Users normally say they did not click or open any links but just to be on the safe side have them change their passwords anyway.

Lessons Learned

1. Checking SPF, DKIM, and DMARC for authentication of a suspected email
2. Leveraging Virus Total, Symantec, and other sandboxes to check for matches of suspected links, websites, and IP addresses
3. Using the GUI email header analyser
